# 1. INTRODUCTION

Ameren Services (Ameren) retained Environmental Resources Management, Inc. (ERM) to prepare this Ambient Air Monitoring Report (AAMR) to document the ambient air conditions that were present during the remediation at the Fifth Street Right-of-Way (ROW) near the former manufactured gas plant (MGP) site located in Champaign, Illinois (Remediation Site). The site activities included excavating MGP-related impacted material, and replacing the MGP-related impacted material with non-impacted backfill material. Ameren completed this work in cooperation with the Illinois Environmental Protection Agency (IEPA) Site Remediation Program (SRP).

This AAMR was prepared to document the ambient air quality monitoring and sampling conducted at the perimeter of the Remediation Site during the remedial activities as part of the project efforts to ensure that remedial activities did not adversely affect the surrounding community. The air monitoring program consisted of real-time perimeter monitoring and time-averaged sampling at four Stationary Air Monitor (SAM) locations (SAM-1 through SAM-4) and one duplicate location (SAM-5) around the perimeter of the Remediation Site. This work was conducted in accordance with the Ambient Air Monitoring Plan (AAMP), dated December 2021, prepared by ERM. This AAMR is intended to summarize the results of the real-time and time-averaged air sampling conducted during remedial activities that occurred between December 2021 to May 2022.

## 1.1 Remediation Site Information and Background

The Remediation Site is associated with the off-site area, approximately 0.75 acres, that borders the west side of the former MGP (Main Site). The Remediation Site includes the North Fifth Street ROW and extends from the Norfolk-Southern railroad track ROW on the north end of the Remediation Site, to approximately 70 feet south of the intersection of North Fifth Street and East Hill Street on the south end of the Remediation Site. The Remediation Site extends west of North Fifth Street to a former residential property (412 East Hill Street), currently owned by Ameren, another former residential property (411 East Hill Street), currently owned by the City of Champaign, as well as a portion of East Hill Street ROW. The Remediation Site is illustrated in Figure 1.

## 1.2 Objectives of the Ambient Air Monitoring Program

The remedial activities conducted at the Remediation Site had the potential to generate fugitive emissions. Ameren implemented an ambient air monitoring program to monitor air quality on a real-time and time-averaged basis. This monitoring program, coupled with appropriate remediation work practices, reduced the potential impact of the remedial activities on ambient air quality in and around the Remediation Site by minimizing the potential for fugitive emissions.

The primary objectives of the ambient air monitoring program were to:

1. Monitor air quality at the Remediation Site perimeter to assess whether fugitive emissions from the remedial activities are impacting ambient concentrations.
2. Evaluate the need for additional engineering controls and/or modifications to remediation work practices based on the results of perimeter air monitoring results.
3. Document air quality conditions throughout remedial activities by the sample collection and analysis of real-time monitoring data.

Specific objectives of the proposed ambient air monitoring program include:

- Conduct real-time ambient air quality monitoring at designated Remediation Site perimeter locations for timely identification of significant emission occurrences to allow for the prompt implementation of necessary corrective measures by the Remediation Contractor.
- Documentation of ambient air quality at designated perimeter locations following completion of remedial activities to assess the potential for residual emissions resulting from the remediation.

- Collect a sufficient quantity of ambient air quality and meteorological data over the course of the monitoring program to support a potential future assessment of impacts to air quality in areas surrounding the Remediation Site resulting from the remedial activity, if necessary.

## 1.3 Remediation Site Activities

Remedial activities consisted of road closure, traffic control, security fence installation, installation of erosion controls, preparation of dewatering, stormwater sewer bypass, utility survey and relocation, road demolition, earth retention system (ERS) installation, and the excavation, transportation, and disposal of approximately 25,000 tons of MGP-related impacted material.

Ambient air monitoring was performed during periods of excavation and backfilling at each phase of remediation. Time-averaged and real-time ambient air monitoring were performed for the duration of the actual remediation action—from December 3, 2021 through May 2, 2022. Pre-remediation air monitoring was also performed prior to initiation of intrusive remedial activities and post-remediation air monitoring was performed following completion of the remediation. Ambient air monitoring methodology and procedures were presented in the AAMP.

# 2. AMBIENT AIR MONITORING PROCEDURES AND METHODOLOGY

This section presents information regarding ambient air sampling parameters, methods, duration and frequency, and meteorological monitoring.

## 2.1 Ambient Air Monitoring Parameters

Time-averaged and real-time ambient air sampling was conducted during the remedial activities to monitor the following parameters:

- Benzene, Toluene, Ethylbenzene, Xylene (BTEX) and Styrene (time-averaged);
- Semi-Volatile and Condensed-Phase Polynuclear Aromatic (PNAs) (time-averaged);
- Total Volatile Organic Compounds (VOCs) (real-time);
- Benzene (real-time); and,
- Coarse Particulate Matter—10 microns or less in aerodynamic diameter ($PM_{10}$) (real-time).

A continuously recording weather system provided on-site wind speed and direction, barometric pressure, and relative humidity measurements to assist in interpreting the air monitoring results.

## 2.2 Real-Time Ambient Air Sampling Methods and Equipment

Real-time ambient air monitoring was performed to measure total volatile organic compounds (VOCs), benzene, and $PM_{10}$. The real-time ambient air sampling methods and equipment are detailed in the following subsections.

### *2.2.1 Total VOCs and Benzene*

Real-time ambient air monitoring for total VOCs was performed using a Mini-RAE 3000 portable photoionization detector (PID) with a 10.6 eV lamp, as a screening device to non-selectively monitor total VOCs. In the event that the measured real-time VOC concentration exceeded the corresponding VOC action level, benzene-specific monitoring was performed at the exceedance location, using a Dräger XPID-8500, portable gas chromatograph (GC).

PID measurements were recorded at the designated perimeter real-time monitoring locations, once per hour during the normal workday. Each measurement was collected by pointing the sample intake toward the work area at breathing zone height at each designated monitoring location. The instrument was allowed to run until a stable reading was detected. The PID measurement was recorded on the field data sheets, along with the time, location, and other relevant information. Qualitative notes regarding the presence and intensity of odors identified, if any, were recorded.

If a sustained PID measurement was observed in excess of 0.5 ppm, a second PID measurement was completed. If the second PID measurement was sustained in excess of 0.5 ppm, the portable GC was used to determine the benzene concentration.

Real-time VOC ambient air monitoring results are discussed in Section 3.1. The benzene Action Level was set at 0.5 parts per million (ppm). If a routine total VOC response exceeded 0.5 ppm, the portable GC was deployed to obtain a benzene-specific concentration. Real-time total VOC field measurements are presented in Appendix A. Real-time VOC monitoring locations are illustrated on Figure 2.

### *2.2.2 Coarse Particulate Matter*

Real-time monitoring of fugitive dust ($PM_{10}$ particulate matter) was conducted using a DustTrak II Aerosol Monitor. Perimeter real-time $PM_{10}$ concentrations were measured to inform the Remediation

Contractor of the need to implement more intensive fugitive emission control measures and/or modify work practices. Any visible off-site dust impacts were addressed regardless of instrument readings.

Measurement of $PM_{10}$ concentrations were made at designated perimeter real-time monitoring locations throughout the remedial activities. Measurements were reduced to 15-minute averages, which were telemetered to a database server via cellular modem, for processing. The $PM_{10}$ inlets were installed at a height of approximately 1.5 meter (i.e., breathing zone). If a sustained $PM_{10}$ particulate measurement was observed to be in excess of an action level of 360 micrograms per cubic meter ($\mu g/m^3$), the Remediation Contractor was notified immediately and corrective actions initiated.

Real-time $PM_{10}$ field measurements are presented in Appendix B. The real-time measurements were telemetered to a dedicated, secure database server for automated processing, including comparison against action levels. In the event of an alert level exceedance, the database server automatically issued an alert via email and/or text message.

Real-time $PM_{10}$ ambient air monitoring results are discussed in Section 3.1. The $PM_{10}$ Action Level was set at 360 $\mu g/m^3$. Operational responses were determined by the magnitude of the concentration, and the duration above the concentration criterion. Real-time $PM_{10}$ monitoring locations are illustrated on Figure 1.

## 2.3 Time-Averaged Ambient Air Sampling Methods and Equipment

Time-averaged volatile and semi-volatile/condensed-phase organic compound ambient air samples were collected at the stationary air monitoring locations along the perimeter of the Remediation Site. Ambient air samples were collected for analysis in general conformance to the United States Environmental Protection Agency (USEPA) Compendium of Methods for Toxic Air Pollutants, specifically, Method TO-13A and Method 325A.

Laboratory analysis was performed by Eurofins Air Toxics, Inc. (Eurofins), at a facility that was certified under the National Environmental Laboratory Accreditation Program (NELAP), in accordance with the aforementioned methods. The time-averaged ambient air sampling methods and equipment are detailed in the following subsections. The time-averaged VOC and semi-volatile/condensed-phase organic compound data are provided in Appendix C and Appendix D, respectively.

### *2.3.1 VOCs*

Time-averaged ambient air sampling for VOCs was performed in accordance with the USEPA Method 325A (USEPA, 2019). Composite VOC samples were collected using passive sorbent tube samplers.

Passive tube samples were mounted beneath a weather hood at each stationary air monitoring location and exposed for a nominal 14-day period. Laboratory analysis was completed in accordance with USEPA Method 325B. Analytes consisted of BTEX and styrene. Sampling was performed from the pre-remediation period, through remediation, and during a post-remediation 14-day period.

### *2.3.2 Semi-Volatile/Condensed-Phase Organic Compounds*

Time-averaged ambient air sampling for semi-volatile/condensed-phase organic compounds was performed in general conformance to USEPA Method TO-13A (USEPA, 1999a). For each sample, a low-volume vacuum pump drew air through a prepared filter/adsorbent cartridge at a nominal volumetric flow rate of two liters per minute. Particulate-bound and condensed-phase compounds were collected on the cartridge's polyurethane foam plugs, while semi-volatile compounds were bound to its contained solid adsorbent. Following sample collection, the cartridge was kept cold (on ice) and protected from light exposure to prevent decomposition of photosensitive compounds. Each sample cartridge was extracted and analysed by USEPA Method TO-13A.

Two Method TO-13A semi-volatile/condensed-phase samples were generally collected per week during active remediation, with the first sample running from Monday morning through mid-day

Wednesday, and the second sample running from mid-day, Wednesday, through conclusion of the remediation work week (Friday or Saturday).

The solid adsorbent sampling system operated using a battery-powered flow-controlled pump. The pump flow rates were set to sample at approximately two liters per minute. At the conclusion of each sampling event, the sample cartridges were prepared for shipping to the lab and repackaged in the laboratory-supplied sample container. The samples were stored on-site in a refrigerated system at a temperature not to exceed 4°C (39°F) and protected from light exposure to prevent decomposition of photo-sensitive compounds. The laboratory extracted and analyzed each sample cartridge (PUF plugs and adsorbant) as one integrated sample.

The samplers were calibrated using an NIST-certified flow meter, in accordance with the manufacturer instructions, prior to the first sampling event and between sampling events thereafter. The calibration consisted of a single point calibration at the target flow rate of 2.0 liters per minute.

The analytical laboratory reported concentrations of target semi-volatile/condensed-phase organic compounds on a mass [per sample basis. These sample results were converted to units of micrograms per cubic meter (µg/m3) using the following equation:

$$Concentration\ (\frac{analyte\ mass\ (\mu g)}{sample\ volume\ (m^3)}) = \frac{Mass\ (\mu g)}{Sample\ flow\ rate\ \left(\frac{m^3}{min}\right) x\ Elapsed\ time\ (min)}$$

## 2.4 Ambient Air Sampling Duration and Frequency

Baseline time-averaged ambient organic compound air sampling was performed in accordance with the USEPA Methods TO-13A, 325A; and $PM_{10}$ with stationary real-time ambient air sampling stations. Measurements were made prior to commencement of remedial activities from December 3, 2021 through December 15, 2021. Remediation monitoring extended from December 15, 2021 through April 29, 2022. Post-remediation monitoring was performed from April 29, 2022 to May 13, 2022.

As previously noted, two Method TO-13A semi-volatile/condensed-phase samples were normally collected per week, with the first sample running from Monday morning through mid-day Wednesday, and the second sample running from mid-day, Wednesday, through conclusion of the remediation work week (Friday or Saturday). A single set of TO-13A samples was collected from the pre-remediation period, and a single set from the post-remediation sampling period.

14-day Method 325A VOC passive samples were collected at each stationary site throughout the remedial activities. Pre-remediation samples were deployed for 12 days due to commencement of remediation, while the post-remediation period was for a full 14 days.

Continuous real-time $PM_{10}$ monitoring was performed during the pre-remediation period, throughout remedial activities, and the post-remediation monitoring period.

Stationary air monitoring site 5 was instrumented with co-located samplers for each sampling method to collect duplicate sample sets for QA/QC purposes.

Real-time ambient total VOC air monitoring was performed during normal site work hours on days when remedial activities occurred, by taking PID measurements at approximately one-hour intervals along the perimeter of the Remediation Site. Real-time VOC monitoring was suspended during unsafe weather conditions.

## 2.5 Meteorological Monitoring

A MetOne AIO2 weather station continuously measured and recorded wind speed, wind direction, barometric pressure, relative humidity, and ambient temperature from December 3, 2021 through May 2, 2022. The meteorological data collection system was installed at stationary air monitoring site 3. In a deviation from the Ambient Air Monitoring Plan, a precipitation sensor was unavailable for

deployment. In lieu of on-site monitored precipitation measurements, the Champaign-Willard Airport weather station precipitation data has been incorporated in the project data record, and qualified as such. The airport weather station is located approximately 6.7 miles from the remediation site.

The record of meteorological data collected is provided in Appendix B.

# 3. AMBIENT AIR MONITORING RESULTS

This section presents the results of the real-time and time-averaged sampling for the ambient air monitoring program.

## 3.1 Real-Time Ambient Air Monitoring Results

Project-specific acceptable air quality exposure levels were developed using risk-based exposure equations for inhalation. The acceptable air quality exposure levels are based on project-specific data, assuming a projected 18-week project duration, and were used to develop a maximum acceptable exposure concentration to a theoretical sensitive receptor. The derivation of the benzene acceptable exposure level, as well as those of other compounds associated with MGP remediation were presented in the AAMP.

Action levels were developed for real-time monitoring and composite air sampling at the Remediation Site using risk-based action levels that were calculated to maintain perimeter air quality at an acceptable level during remedial activities. The real-time action levels were established to serve as an indicator of acceptable short-term air quality and to identify when supplemental emission control responses are necessary. The real-time action levels were developed using air quality workplace and ambient air standards, the capability of the field screening and analytical instruments, and knowledge of MGP constituents of concern (COCs).

Real-time air quality measurements of $PM_{10}$ and VOC concentrations were collected at the four SAMs. In addition, real-time VOCs were measured at the intermediate perimeter monitoring locations (see Figure 2).

### *3.1.1 VOCs Ambient Air Monitoring Results*

The National Institute for Occupational Safety and Health (NIOSH) and the Occupational Safety and Health Administration (OSHA) time weighted average (TWA) exposure standard for benzene (a target VOC) is 1.0 ppm. One-half of the OSHA action level, 0.5 ppm, was selected as the short averaging time action level for VOC, as measured with field instruments. If a total VOC sample was observed to be over 0.5 ppm, the portable GC was deployed to measure benzene. The action level was used to make decisions regarding implementation of more intense emission control measures.

The benzene remediation activity shut-down criterion presented in the AAMP was not met during remedial activities. The real-time VOC action level was exceeded on one occasion during the remedial activities, triggering follow-up benzene-specific monitoring with the portable GC. This occurred at approximately 09:30 on March 25, 2022 at IMPL locations B, C, D, and E. In this instance, the Remediation Contractor was notified and implemented corrective action measures, including a modification to work practices.

In response to the elevated VOC measurement, the field air monitoring technician performed a calibration verification of the GC and deployed it at the location at which the elevated VOC concentration had been measured in order to measure the benzene-specific concentration. The total VOC measurement was repeated using the PID instrument. This showed that the total VOC concentration had decreased to zero, therefore, no GC measurement was performed.

### *3.1.2 $PM_{10}$ Ambient Air Monitoring Results*

The acceptable exposure level (AEL) for $PM_{10}$ was set at the corresponding 24-hour average National Ambient Air Quality Standard of 150 microgram per cubic meter (µg/m3). A 15-minute average action level of 360 µg/m3 served as a conservative short-term surrogate for the AEL. A 15-minute period exceeding ten times the action level would have required suspension of remedial activities.

The $PM_{10}$ shut-down criteria presented in the AAMP were not met during the remedial activities. The real-time $PM_{10}$ action level was also never exceeded during remediation. The real-time $PM_{10}$, VOC, and benzene measurements are summarized in Table 3-1. The real-time VOC and $PM_{10}$ data records are presented in Appendix A and Appendix B, respectively.

**Table 3-1. Real-Time Data—Results Summary**

| Constituents of Concern (Sampling period, Units) | Monitoring Period | Number of Action Level Exceedances | Maximum Measured Concentration | Location of Maximum | Date of Maximum | Action Level |
|---|---|---|---|---|---|---|
| Inhalable Particulate Matter (15-min average, µg/m$^3$) | 12/3/22 – 5/2/22 | 0 | 195 | SAM-4 | 12/27/2021 | 360 |
| VOC (1-minute average, ppm) | 12/5/2022 – 5/20/22 | 1 | 0.6 | IMPL-E | 3/25/2022 | 0.5 |
| Benzene, Real-time GC (1-minute average ppm) | 12/5/2022 – 5/20/22 | 0 | NM | NM | NM | 0.5 |

NM = No measurements (benzene-specific measurements only made with portable gas chromatograph, in response to VOC exceedance)

## 3.2 Time-Averaged Monitoring Results

This section describes the time-averaged results for volatile and semi-volatile/condensed phase organic compounds. The air quality acceptable exposure levels for the BTEX, styrene, as well as for selected semi-volatile/condensed-phase polynuclear aromatic (PNA) compounds for the nominal 18-week exposure period were developed in the AAMP.

The maximum observed concentrations of these target species, over the course of the remedial activities are summarized in Table 3-2. The complete VOC and semi-volatile/condensed-phase organic compound data records are tabulated in Appendix C and Appendix D, respectively.

Laboratory analytical services were provided by Eurofins Air Toxics, Inc. The Method 325B laboratory analytical reports are provided in Appendix E. The TO-13A laboratory analytical reports are presented in Appendix F.

**Table 3-2. Time-Averaged Volatile and Semi-Volatile/Condensed-Phase Organic Compound Concentrations—Results Summary**

| Constituents of Concern, Method (Sampling period, Units) | Number of Action Level or Acceptable Exposure Level Exceedances | Maximum Measured Concentration | Acceptable Exposure Level |
|---|---|---|---|
| Styrene, Method 325B (14-day sample period, µg/m$^3$) | 0 | 0.26 | 157.7 |
| Benzene, Method 325B (14-day sample period, µg/m$^3$) | 0 | 0.74 | 16.5 |
| Toluene, Method 325B (14-day sample period, µg/m$^3$) | 0 | 0.77 | 159.7 |
| Xylenes (total), Method 325B (14-day sample period, µg/m$^3$) | 0 | 0.29 | 160.7 |
| Ethylbenzene, Method 325B (14-day sample period, µg/m$^3$) | 0 | 0.28 | 161.7 |
| 2-methylnapthalene, Method TO-13A (2-day sample period, µg/m$^3$) | 0 | 0.63* | 820 |
| Acenaphthene, Method TO-13A (2-day sample period, µg/m$^3$) | 0 | ND | 12,300 |
| Acenaphthylene, Method TO-13A (2-day sample period, µg/m$^3$) | 0 | ND | 615 |
| Anthracene, Method TO-13A (2-day sample period, µg/m$^3$) | 0 | ND | 615 |
| Benzo(a)anthracene, Method TO-13A (2-day sample period, µg/m$^3$) | 0 | ND | 1.54 |
| Benzo(a)pyrene, Method TO-13A (2-day sample period, µg/m$^3$) | 0 | ND | 0.154 |
| Benzo(k)fluoranthene, Method TO-13A (2-day sample period, µg/m$^3$) | 0 | ND | 15.4 |
| Benzo(b)fluoranthene, Method TO-13A (2-day sample period, µg/m$^3$) | 0 | ND | 15.4 |
| Chrysene, Method TO-13A (2-day sample period, µg/m$^3$) | 0 | ND | 154 |
| Dibenzo(a,h)anthracene, Method TO-13A (2-day sample period, µg/m$^3$) | 0 | ND | 0.154 |
| Fluoranthene, Method TO-13A (2-day sample period, µg/m$^3$) | 0 | ND | 8,200 |
| Fluorene, Method TO-13A (2-day sample period, µg/m$^3$) | 0 | ND | 8,200 |
| Indeno(1,2,3-cd)pyrene, Method TO-13A (2-day sample period, µg/m$^3$) | 0 | ND | 1.54 |
| Napthalene, Method TO-13A (2-day sample period, µg/m$^3$) | 0 | 3.72* | 176 |
| Phenanthrene, Method TO-13A (2-day sample period, µg/m$^3$) | 0 | ND | 6,150 |
| Pyrene, Method TO-13A (2-day sample period, µg/m$^3$) | 0 | ND | 6,150 |

ND = Not detected (concentrations below laboratory minimum detection limits)

* = Nominal 2 LPM sample flow used to calculate concentration during this 2-day sample.

### *3.2.1 VOCs Monitoring Results*

Site-specific risk-based acceptable concentration levels, as described above, were calculated for all the targeted VOCs associated with the remedial activities, as derived in the AAMP. The site-specific risk-based acceptable exposure level for benzene is 16.5 µg/m$^3$.

As Table 3-1 illustrates, all the USEPA Method 325B analytes in all the samples collected during the remedial activities were below the risk-based air quality objective concentrations. With respect to benzene, the calculated acceptable risk concentration was 16.5 µg/m$^3$. The measured 14-day average benzene concentrations were all below this concentration at each monitoring location, with maximum concentrations ranging from 0.63 µg/m$^3$ at SAM-5 to 0.74 µg/m$^3$ at SAM-2 during the remedial activities (Table 3-3).

**Table 3-3. Time-Averaged Volatile Organic Compounds, Maximum Measured Values**

| Sample Location | COMPOUND | DL | Results µg/m$^3$ |
|---|---|---|---|
| SAM1 | Benzene | 0.38 | 0.71 |
| | Ethyl Benzene | 0.56 | 0.28 |
| | Styrene | 0.52 | 0.26 |
| | Toluene | 0.50 | 0.77 |
| | m,p-Xylene | 0.56 | 0.39 |
| | o-Xylene | 0.56 | 0.29 |
| SAM2 | Benzene | 0.38 | 0.74 |
| | Ethyl Benzene | 0.56 | 0.28 |
| | Styrene | 0.52 | 0.26 |
| | Toluene | 0.50 | 0.65 |
| | m,p-Xylene | 0.56 | 0.35 |
| | o-Xylene | 0.56 | 0.28 |
| SAM3 | Benzene | 0.38 | 0.71 |
| | Ethyl Benzene | 0.56 | 0.28 |
| | Styrene | 0.52 | 0.26 |
| | Toluene | 0.50 | 0.71 |
| | m,p-Xylene | 0.56 | 0.36 |
| | o-Xylene | 0.56 | 0.29 |
| SAM4 | Benzene | 0.38 | 0.68 |
| | Ethyl Benzene | 0.56 | 0.28 |
| | Styrene | 0.52 | 0.26 |
| | Toluene | 0.50 | 0.62 |
| | m,p-Xylene | 0.56 | 0.35 |
| | o-Xylene | 0.56 | 0.28 |
| SAM5 | Benzene | 0.38 | 0.63 |
| | Ethyl Benzene | 0.56 | 0.28 |
| | Styrene | 0.52 | 0.26 |
| | Toluene | 0.50 | 0.56 |
| | m,p-Xylene | 0.56 | 0.30 |
| | o-Xylene | 0.56 | 0.28 |

### *3.2.2 Semi-Volatile/Condensed Phase Organic Compounds Monitoring Results*

Site-specific risk-based air quality objective concentrations, as described above, were calculated for targeted semi-volatile/condensed-phase organic compounds associated with the remedial activities, and were derived in the AAMP.

Laboratory analytical results for USEPA Method TO-13A indicate that all the measured targeted semi-volatile/condensed-phase organic compound concentrations for time-averaged samples collected during the remedial activities at all monitoring sites were below their respective risk-based air quality objective concentrations.

Semi-volatile/condensed-phase organic compound values were reported by the laboratory as mass, in µg per sample. The laboratory results were converted to air concentration concentrations (expressed as µg/m3) using flow rate calibration data and sample event elapsed time. Table 3-1 contains a summary of semi-volatile/condensed-phase concentrations measured during the monitoring program.

## 3.3 Meteorological Monitoring Results

On-site meteorological data were collected using a MetOne AIO2 weather station that continuously measured wind speed, wind direction, barometric pressure, relative humidity, and ambient temperature during the project duration. The weather station data were recorded and tabulated for each of the aforementioned parameters once per 15-minute interval on average. Site meteorological data were collected for the duration of project (i.e., December 3, 2021 through May 2, 2022). As noted above, precipitation data was accessed from the Champaign Willard Airport weather station and incorporated into the database. The complete meteorological data record is presented in Appendix B.

# 4. QUALITY ASSURANCE/QUALITY CONTROL

Standard Operating Procedures (SOPs) were followed to ensure the quality of the data collected during implementation of the ambient air quality monitoring program. Calibrations were performed regularly to maintain accurate measurements. Calibration documentation is presented in Appendix G. Analytical methods chosen for time-averaged monitoring samples were approved USEPA methods. In addition, blanks and duplicate samples were submitted for Method 325B and TO-13A analysis.

## 4.1 Real-Time Monitoring Equipment

Real-time monitoring equipment calibrations during the remediation program were performed as follows:

- The total VOC PID meter was calibrated each morning before commencing perimeter monitoring, with 100 ppm isobutylene certified calibration gas;
- The GC was calibrated by the vendor and its performance verified prior to field use by challenge with certified calibration gas. The vendor calibration documentation is presented in Appendix G.

## 4.2 Time-Averaged Sampling Equipment

Calibrations and maintenance for time-averaged ambient air monitoring equipment were performed in accordance with manufacturer instructions as follows:

- Semi-volatile/condensed-phase TO-13A ambient air sampling pumps were calibrated daily;
- Real-time $PM_{10}$ monitor flow rates were verified daily;
- Stationary time-averaged $PM_{10}$ ambient air monitoring size-selective inlets were cleaned after every 15 days (on average) of sampling and impactor oil refreshed.

Calibration field logs, field data, including Remediation Site and sample notations, real time measurements, monitoring locations, and parameters were documented on field data sheets. These are provided in Appendix H.

## 4.3 Meteorological Monitoring

Meteorological data were collected on a continuous daily basis during the project duration. The meteorological data collected onsite were: atmospheric temperature, atmospheric pressure, relative humidity, wind speed, and wind direction. As discussed above, precipitation data from the Champaign Willard Airport weather station were accessed and incorporated into the data record. The wind vane was aligned per manufacturer's instructions. Meteorological sensors were calibrated by the supplier prior to shipment and properly oriented in accordance with manufacturer's instructions.

## 4.4 Time-Averaged Sampling Quality Assurance/Quality Control (QA/QC)

The Quality Assurance/Quality Control (QA/QC) procedures that were followed for collection of ambient air quality samples include the use of field and travel blanks, and duplicate samples. Field duplicate sample results indicate the precision and reproducibility of sample collection and analytical results. The project goal was to collect a minimum of 5 percent (i.e., 1 in 20) duplicate samples per sampling event. Field blank and trip blank results were used to assess sample integrity. The results of these analyses allow an evaluation of whether measurements may be biased by chemicals introduced into the samples during handling or sample shipping. The QC samples collected were as follows:

- VOC (USEPA Method 325A/B) - one duplicate sample and one field blank per shipment during each remediation and post-remediation sampling event.
- Semi-volatile/condensed-phase (USEPA Method TO-13A) - one duplicate sample and one field blank per shipment during each remediation and post-remediation sampling event.

All samples were shipped to the laboratory and analysed within the applicable methods recommended holding times. Laboratory QC was performed in accordance with the method requirements for USEPA Methods TO-13A, and 325A/B.

## 4.5 Laboratory Data Validation

Data validation assesses the quality of field and laboratory activities and documents the quality of data generated by evaluating precision, accuracy, representativeness, comparability, and completeness. The goal of the validation process is to produce a technically sound, statistically valid, defensible, and properly documented data set for decision-making purposes. General information pertaining to verification and validation activities is provided in the *Guidance on Environmental Data Verification and Data Validation, EPA QA/G-8* (USEPA, 2008).

Following analysis, the laboratory analytical report was verified for conformance with method, procedural, and contractual requirements. The contracted laboratory was responsible for accurately performing the prescribed methods, per USEPA protocols. This includes all procedures, QC checks, corrective actions, and data handling. In general, chemical data were validated by evaluation of the laboratory submittal against any requirements, established in the analytical method.

If the QA/QC sample results were outside criteria established in the analytical method, data qualifiers were added to the results using guidelines presented in the *USEPA Contract Laboratory Program National Functional Guidelines for Superfund Organic Methods Data Review (NFGO), EPA-540-R-14-002* (USEPA, 2014a) and *USEPA Contract Laboratory Program National Functional Guidelines for Inorganic Superfund Data Review (NFGI), EPA-540-R-13-001 (USEPA, 2014b).*

Laboratory data have been reviewed and are acceptable for use with additional qualification by ERM where necessary. Eurofins Air Toxics, Inc. performed laboratory validation and determined that all analytical results were usable with qualification. Volatile and semi-volatile/condensed-phase laboratory analytical reports are provided in Appendix E and Appendix F, respectively.
